Defintion

Graph: $G = (V, E)$ with vertex set V and edge set $E \subseteq \binom{V}{2}$.

- All graphs in this talk are undirected and simple.
- The adjacency matrix A of a graph Γ is the matrix whose rows and columns are indexed by its vertices such that $A_{xy} = 1$ if xy is an edge and 0 otherwise.

- A root lattice is an integral lattice, generated by norm 2 vectors.
- If Λ can be written as the orthogonal sum of two proper sublattices we say Λ is reducible, and otherwise it is called irreducible.
- We say an integral lattice is *s-integrable* if $\sqrt{s}\Lambda$ is isomorphic to a sublattice of the standard lattice.

Root Lattices

- Let e_1, \dots, e_n the standard basis of R^n .

Root Lattices

- Let e_1, \dots, e_n the standard basis of R^n .
- A_n is the root lattice generated by $\{e_i - e_j \mid 1 \leq i, j \leq n+1, i \neq j\}$ ($n \geq 1$).
- D_n is the root lattice generated by $\{e_i - e_j, e_i + e_j \mid 1 \leq i, j \leq n\}$.

Root Lattices

- Let e_1, \dots, e_n the standard basis of R^n .
- A_n is the root lattice generated by $\{e_i - e_j \mid 1 \leq i, j \leq n+1, i \neq j\}$ ($n \geq 1$).
- D_n is the root lattice generated by $\{e_i - e_j, e_i + e_j \mid 1 \leq i, j \leq n\}$.

Theorem

(Witt (1941)) *The only irreducible root lattices are A_n , D_n and E_6, E_7, E_8 .*

The root lattices E_6 , E_7 and E_8 are 2-integrable, but can not be 1-integrated.

A basis of E_8

$$N = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 & 2 & 1 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & -1 & 0 & 0 & 0 & 0 & 0 \\ 1 & 0 & 1 & 2 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 2 & 1 & 0 \\ -1 & 0 & 0 & 0 & 1 & 0 & -1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 2 \\ -1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \end{pmatrix}$$

- $21 \leq c(4) \leq 25$, $16 \leq c(5) \leq 22$,
- $c(s) = O(s)$

Results of Conway and Sloane

Definitions

Let s be a positive integer. We define $c(s)$ as the smallest positive integer t such that there exists an integral lattice Λ with $\dim(\Lambda) = t$, that can not be s -integrated. It is not a priori clear that this number exists.

Conway and Sloane (1989) showed:

Theorem

- $c(1) = 6, c(2) = 12, c(3) = 14,$
- $21 \leq c(4) \leq 25, 16 \leq c(5) \leq 22,$
- $c(s) = O(s)$
- $c(s) \rightarrow \infty \quad (s \rightarrow \infty)$

Some Remarks

- $c(1) = 6$ was shown by Ko and Mordell (1937). (Ko of Erdős-Ko-Rado)

Some Remarks

- $c(1) = 6$ was shown by Ko and Mordell (1937). (Ko of Erdős-Ko-Rado)
- Lagrange theorem states that every positive integer can be written as the sum of four squares. This means that any 1-dimensional lattice is isomorphic to a sublattice of Z^4 .

Some Remarks

- $c(1) = 6$ was shown by Ko and Mordell (1937). (Ko of Erdős-Ko-Rado)
- Lagrange theorem states that every positive integer can be written as the sum of four squares. This means that any 1-dimensional lattice is isomorphic to a sublattice of Z^4 .
- Conway and Sloane also generalized this result for higher dimensional lattices, i.e. they showed that you only need a few extra dimensions to make the lattice s -integrable.

Some Remarks

- $c(1) = 6$ was shown by Ko and Mordell (1937). (Ko of Erdős-Ko-Rado)
- Lagrange theorem states that every positive integer can be written as the sum of four squares. This means that any 1-dimensional lattice is isomorphic to a sublattice of Z^4 .
- Conway and Sloane also generalized this result for higher dimensional lattices, i.e. they showed that you only need a few extra dimensions to make the lattice s -integrable.
- The main idea of Conway and Sloane is that for any integral lattice Λ , there exists a unimodular lattice Λ' that contains Λ as a sublattice and $\dim(\Lambda') - \dim(\Lambda)$ is at most three.

Some Remarks

- $c(1) = 6$ was shown by Ko and Mordell (1937). (Ko of Erdős-Ko-Rado)

Smallest eigenvalue -2

Definition

We say a connected graph G with smallest eigenvalue at least -2 and adjacency matrix A is a **generalized line graph** if there exists an integral matrix N such that $A + 2I = N^T N$.

Smallest eigenvalue -2

Definition

We say a connected graph G with smallest eigenvalue at least -2 and adjacency matrix A is a **generalized line graph** if there exists an integral matrix N such that $A + 2I = N^T N$.

Note that if I can take N with entries only 0's and 1's, then G is a line graph. So a generalized line graph is a generalization of a line graph.

The following beautiful result was shown by Cameron, Goethals, Seidel, and Shult (1976):

Theorem

Let G be a connected graph with smallest eigenvalue at least -2 . Then either G has at most 36 vertices or G is a generalized line graph.

The following beautiful result was shown by Cameron, Goethals, Seidel, and Shult (1976):

Theorem

Let G be a connected graph with smallest eigenvalue at least -2 . Then either G has at most 36 vertices or G is a generalized line graph.

We give now a sketch of proof for this result, as we will need this idea later in the talk.

Sketch of proof

- Let G be a connected graph with smallest eigenvalue at least -2 .

Sketch of proof

- Let G be a connected graph with smallest eigenvalue at least -2 .
- Then $A + 2I$ is positive semidefinite, so it is a Gram matrix
 $A + 2I = N^T N$.

Sketch of proof

- Let G be a connected graph with smallest eigenvalue at least -2 .
- Then $A + 2I$ is positive semidefinite, so it is a Gram matrix
 $A + 2I = N^T N$.
- Let Λ be the integral lattice generated by the columns of N .

Sketch of proof

- Let G be a connected graph with smallest eigenvalue at least -2 .
- Then $A + 2I$ is positive semidefinite, so it is a Gram matrix $A + 2I = N^T N$.
- Let Λ be the integral lattice generated by the columns of N .
- Then Λ is an even lattice, generated by norm two vectors, so it is a root lattice and it is irreducible as G is connected.

Sketch of proof

- Let G be a connected graph with smallest eigenvalue at least -2 .
- Then $A + 2I$ is positive semidefinite, so it is a Gram matrix $A + 2I = N^T N$.
- Let Λ be the integral lattice generated by the columns of N .
- Then Λ is an even lattice, generated by norm two vectors, so it is a root lattice and it is irreducible as G is connected.
- The irreducible root lattices were classified by Witt, and are of type A_n , D_n or E_6, E_7, E_8 .

Sketch of proof

- Let G be a connected graph with smallest eigenvalue at least -2 .
- Then $A + 2I$ is positive semidefinite, so it is a Gram matrix $A + 2I = N^T N$.
- Let Λ be the integral lattice generated by the columns of N .
- Then Λ is an even lattice, generated by norm two vectors, so it is a root lattice and it is irreducible as G is connected.
- The irreducible root lattices were classified by Witt, and are of type A_n , D_n or E_6, E_7, E_8 .
- The first two lattices give us generalized line graphs, and for the last three lattices one can show that the number of vertices is at most 36.

Smallest eigenvalue $-1 - \sqrt{2}$

Hoffman (1977) showed the following result:

Theorem

Let $2 < \lambda < 1 + \sqrt{2}$. Then there is constant $K = K(\lambda)$ such that if Γ is a connected graph with minimal valency at least K and smallest eigenvalue $\lambda_{\min} \geq -\lambda$, then Γ is a generalised line graph. In particular, $\lambda_{\min} \geq -2$.

- This result means that there exists a real number $\tau(k) < -2$ such that any connected graph with minimal valency at least k has smallest eigenvalue either at least -2 or at most $\tau(k)$, and $\tau(k) \rightarrow -1 - \sqrt{2}$ ($k \rightarrow \infty$).

- Hoffman did not use the classification of irreducible root lattices, but he needed to pay the price by assuming large minimal valency.

- Hoffman did not use the classification of irreducible root lattices, but he needed to pay the price by assuming large minimal valency.
- Woo and Neumaier (1995) generalized this result by Hoffman by going slightly below $-1 - \sqrt{2}$.

Rephrasing the results of Cameron et al. and Hoffman

As the generalised line graphs are exactly the graphs with smallest eigenvalue at least -2 which are 1-integrable, we can rephrase the results of Cameron et al. and Hoffman as follows:

Theorem

Let G be a connected graph with smallest eigenvalue at least -2 . Then G is 2-integrable.

Rephrasing the results of Cameron et al. and Hoffman

As the generalised line graphs are exactly the graphs with smallest eigenvalue at least -2 which are 1-integrable, we can rephrase the results of Cameron et al. and Hoffman as follows:

Theorem

Let G be a connected graph with smallest eigenvalue at least -2 . Then G is 2-integrable.

Theorem

Let $2 \geq \lambda < 1 + \sqrt{2}$. Then there is constant $K = K(\lambda)$ such that if Γ is a connected graph with minimal valency at least K and smallest eigenvalue $\lambda_{\min} \geq -\lambda$, then $\lambda_{\min}(\Gamma) \geq -2$ and Γ is 1-integrable.

Can we generalize these two results to graphs with smallest eigenvalue at least -3 ?

Can we generalize these two results to graphs with smallest eigenvalue at least -3 ? In this talk we will show a generalization of the result of Hoffman, and that to generalize the first result is probably difficult.

Main result

Our main result is:

Theorem

There exists a constant $K > 0$ such that any connected graph G with minimal valency at least K and λ_{\min} at least -3 is 2-integrable.

Remarks

- The meaning is that a graph with large minimal valency and λ_{\min} at least -3 is still a structured graph, like a generalized line graph, but of course more complicated than a generalized line graph.

Remarks

- The meaning is that a graph with large minimal valency and λ_{\min} at least -3 is still a structured graph, like a generalized line graph, but of course more complicated than a generalized line graph.
- Using the regular two-graph on 276 vertices, K., Munemasa, Rehman and Yang showed that $K \geq 166$.

Remarks

- The meaning is that a graph with large minimal valency and λ_{\min} at least -3 is still a structured graph, like a generalized line graph, but of course more complicated than a generalized line graph.
- Using the regular two-graph on 276 vertices, K., Munemasa, Rehman and Yang showed that $K \geq 166$.
- We only know an implicit upper bound for K , but certainly our bound is far from the true value.

Remarks

- The meaning is that a graph with large minimal valency and λ_{\min} at least -3 is still a structured graph, like a generalized line graph, but of course more complicated than a generalized line graph.
- Using the regular two-graph on 276 vertices, K., Munemasa, Rehman and Yang showed that $K \geq 166$.
- We only know an implicit upper bound for K , but certainly our bound is far from the true value.
- We have a family of connected non 2-integrable graphs with unbounded number of vertices and smallest eigenvalue at least -3 . So this means that the result of Cameron et al. is not so easy to be generalized.

Representations

- The proof is a combination of the techniques used in the result of Cameron et al. of 1976 and the result of Hoffman of 1977. I will only give the main idea behind the proof.

Representations

- The proof is a combination of the techniques used in the result of Cameron et al. of 1976 and the result of Hoffman of 1977. I will only give the main idea behind the proof.
- We first need to discuss representations of graphs

Representations of graphs

- A representation of a graph G with norm m is a map $x \mapsto \bar{x}$ satisfying
 - $\langle \bar{x}, \bar{x} \rangle = m$
 - $\langle \bar{x}, \bar{y} \rangle = 1$ if $x \sim y$ and 0 otherwise.

Representations of graphs

- A representation of a graph G with norm m is a map $x \mapsto \bar{x}$ satisfying
 - $\langle \bar{x}, \bar{x} \rangle = m$
 - $\langle \bar{x}, \bar{y} \rangle = 1$ if $x \sim y$ and 0 otherwise.
- A representation of G is called **fat** if there exists a set U of orthonormal vectors such that
 - for all $x \in V(G)$ and all $u \in U$, the inner product $\langle \bar{x}, u \rangle \in \{0, 1\}$, and
 - for any $x \in V(G)$, there exists $u \in U$ such that $\langle \bar{x}, u \rangle = 1$.

Main result

The following result implies our main result.

Main result

The following result implies our main result.

Theorem

There exists a positive constant K such that any connected graph G with minimal valency at least K and λ_{\min} at least -3 has a fat representation of norm 3.

Main result

The following result implies our main result.

Theorem

There exists a positive constant K such that any connected graph G with minimal valency at least K and λ_{\min} at least -3 has a fat representation of norm 3.

- Now we take the orthogonal projection on the orthogonal complement of subspace generated by the set U of the fat representation, to obtain the representation $x \mapsto \tilde{x}$.

Main result

The following result implies our main result.

Theorem

There exists a positive constant K such that any connected graph G with minimal valency at least K and λ_{\min} at least -3 has a fat representation of norm 3.

- Now we take the orthogonal projection on the orthogonal complement of subspace generated by the set U of the fat representation, to obtain the representation $x \mapsto \tilde{x}$.
- Note $\langle \tilde{x}, \tilde{x} \rangle \leq 2$ and $\langle \tilde{x}, \tilde{y} \rangle \in \mathbb{Z}$.

Main result

The following result implies our main result.

Theorem

There exists a positive constant K such that any connected graph G with minimal valency at least K and λ_{\min} at least -3 has a fat representation of norm 3.

- Now we take the orthogonal projection on the orthogonal complement of subspace generated by the set U of the fat representation, to obtain the representation $x \mapsto \tilde{x}$.
- Note $\langle \tilde{x}, \tilde{x} \rangle \leq 2$ and $\langle \tilde{x}, \tilde{y} \rangle \in \mathbb{Z}$.
- So now we are done by the classification of the root lattices and the fact that they are all 2-integrable.

- To show our fat representation result we first showed, that there only finitely many (non-isomorphic) minimal vertex-weighted signed graphs with smallest eigenvalue < -2 :

- To show our fat representation result we first showed, that there only finitely many (non-isomorphic) minimal vertex-weighted signed graphs with smallest eigenvalue < -2 :
- The first step is that we need to consider vertex-weighted signed graphs $\hat{G} = ((G = V(G), E(G)), w : V(G) \rightarrow \mathbb{Z}_{\leq 0}, \sigma : E(G) \rightarrow \{+1, -1\})$.
- The adjacency matrix of \hat{G} is the symmetric matrix A with entries $A_{xx} = w(x)$, $A_{xy} = \sigma(xy)$ if $xy \in E(G)$ and 0 otherwise.

- To show our fat representation result we first showed, that there only finitely many (non-isomorphic) minimal vertex-weighted signed graphs with smallest eigenvalue < -2 :
- The first step is that we need to consider vertex-weighted signed graphs $\hat{G} = ((G = V(G), E(G)), w : V(G) \rightarrow \mathbb{Z}_{\leq 0}, \sigma : E(G) \rightarrow \{+1, -1\})$.
- The adjacency matrix of \hat{G} is the symmetric matrix A with entries $A_{xx} = w(x)$, $A_{xy} = \sigma(xy)$ if $xy \in E(G)$ and 0 otherwise.
- The eigenvalues of \hat{G} are those of its adjacency matrix.

A result of Vijayakumar

- Vijayakumar (1987) showed that a minimal signed graph \hat{G} with $\lambda_{\min} < -2$, has at most 10 vertices.

A result of Vijayakumar

- Vijayakumar (1987) showed that a minimal signed graph \hat{G} with $\lambda_{\min} < -2$, has at most 10 vertices.
- He first showed that \hat{G} with $\lambda_{\min} \geq -2$, such that its corresponding lattice is not 1-integrable, has at most 6 vertices.

A result of Vijayakumar

- Vijayakumar (1987) showed that a minimal signed graph \hat{G} with $\lambda_{\min} < -2$, has at most 10 vertices.
- He first showed that \hat{G} with $\lambda_{\min} \geq -2$, such that its corresponding lattice is not 1-integrable, has at most 6 vertices.
- Then he used the classification of root lattices and that \hat{G} has exactly one eigenvalue at most -2 , by the star-complement method and interlacing.

Minimal forbidden vertex-weighted signed graphs

- Now we look at minimal vertex-weighted signed graphs with smallest eigenvalue < -2 .

Minimal forbidden vertex-weighted signed graphs

- Now we look at minimal vertex-weighted signed graphs with smallest eigenvalue < -2 .
- Using the proof of the Ostrowski-Hoffman limit theorem, for a vertex x with weight $w(x) < 0$, we join x to a large enough clique and replace $w(x)$ by weight $w(x) + 1$ and the vertices of the clique have weight 0 and keep the weight of the other vertices, and still keeping the eigenvalue less than -2 .

Minimal forbidden vertex-weighted signed graphs

- Now we look at minimal vertex-weighted signed graphs with smallest eigenvalue < -2 .
- Using the proof of the Ostrowski-Hoffman limit theorem, for a vertex x with weight $w(x) < 0$, we join x to a large enough clique and replace $w(x)$ by weight $w(x) + 1$ and the vertices of the clique have weight 0 and keep the weight of the other vertices, and still keeping the eigenvalue less than -2 .
- By repeating the procedure we obtain the minimal graphs with a fat representation of norm > 3 .

Minimal forbidden vertex-weighted signed graphs

- Now we look at minimal vertex-weighted signed graphs with smallest eigenvalue < -2 .
- Using the proof of the Ostrowski-Hoffman limit theorem, for a vertex x with weight $w(x) < 0$, we join x to a large enough clique and replace $w(x)$ by weight $w(x) + 1$ and the vertices of the clique have weight 0 and keep the weight of the other vertices, and still keeping the eigenvalue less than -2 .
- By repeating the procedure we obtain the minimal graphs with a fat representation of norm > 3 .
- Then it is fairly easy to finish the proof of our fat representation result.

- Can we classify those lattices Λ' ?

- Let M be a maximal set of norm 3 vectors of Λ' such that if $u \in M$ then $-u \notin M$.

- Let M be a maximal set of norm 3 vectors of Λ' such that if $u \in M$ then $-u \notin M$.
- Take the Gram matrix B of M .
- Then $B_{ii} = 3$ and $B_{ij} \in \{1, 0, -1\}$.

- Let M be a maximal set of norm 3 vectors of Λ' such that if $u \in M$ then $-u \notin M$.
- Take the Gram matrix B of M .
- Then $B_{ii} = 3$ and $B_{ij} \in \{1, 0, -1\}$.
- So $B - 3I$ is the adjacency matrix of a signed graph \hat{G} with smallest eigenvalue at least -3 .
- Without loss of generality we may assume that \hat{G} is connected.

- Let M be a maximal set of norm 3 vectors of Λ' such that if $u \in M$ then $-u \notin M$.
- Take the Gram matrix B of M .
- Then $B_{ii} = 3$ and $B_{ij} \in \{1, 0, -1\}$.
- So $B - 3I$ is the adjacency matrix of a signed graph \hat{G} with smallest eigenvalue at least -3 .
- Without loss of generality we may assume that \hat{G} is connected.
- Is our main result also true for signed graphs? We define the minimal valency of \hat{G} as that of its underlying graph G .

- Is our main result also true for signed graphs? We define the minimal valency of \hat{G} as that of its underlying graph G .
- I think so, but to show this we need to develop a theory of signed Hoffman graphs.

Some conjectures

Conjectures

- There exists a positive integer s such that any connected graph with smallest eigenvalue at least -3 is s -integrable. (Maybe $s = 4$?)

Some conjectures

Conjectures

- There exists a positive integer s such that any connected graph with smallest eigenvalue at least -3 is s -integrable. (Maybe $s = 4$?)
- Our main result also holds for signed graphs.

- Our main result also holds for signed graphs.
- There exists a positive integer s such that any connected signed graph with smallest eigenvalue at least -3 is s -integrable. (Maybe $s = 4$?)

The last conjecture would essentially give a classification of the lattices with minimum norm 3.

Question:

- Can we extend our result to smallest eigenvalue -4 ?
- Our method can not be extended to -4 , because there are infinitely many minimal forbidden vertex-weighted signed graphs with smallest eigenvalue < -3 .

Thank you for your attention.
